In this chapter, you will learn...

- the closed economy Solow model
- how a country’s standard of living depends on its saving and population growth rates
- how to use the “Golden Rule” to find the optimal saving rate and capital stock

Why growth matters

- Anything that affects the long-run rate of economic growth – even by a tiny amount – will have huge effects on living standards in the long run.

| Annual growth rate of income per capita | Percentage increase in standard of living after...

Why growth matters

- If the annual growth rate of U.S. real GDP per capita had been just one-tenth of one percent higher during the 1990s, the U.S. would have generated an additional $496 billion of income during that decade.

The Solow model

- due to Robert Solow, won Nobel Prize for contributions to the study of economic growth
- a major paradigm:
  - widely used in policy making
  - benchmark against which most growth theories are compared
- looks at the determinants of economic growth and the standard of living in the long run
How Solow model is different from Chapter 3’s model

1. $K$ is no longer fixed: investment causes it to grow, depreciation causes it to shrink
2. $L$ is no longer fixed: population growth causes it to grow
3. the consumption function is simpler

4. no $G$ or $T$ (only to simplify presentation; we can still do fiscal policy experiments)
5. cosmetic differences

The production function

- In aggregate terms: $Y = F(K, L)$
- Define: $y = Y/L = \text{output per worker}$
  $k = K/L = \text{capital per worker}$
- Assume constant returns to scale:
  $zY = F(zK, zL)$ for any $z > 0$
- Pick $z = 1/L$. Then
  $Y/L = F(K/L, 1)$
  $y = F(k, 1)$
  $y = f(k)$ where $f(k) = F(k, 1)$

The consumption function

- $s$ = the saving rate, the fraction of income that is saved
  ($s$ is an exogenous parameter)
- Consumption function: $c = (1-s)y$ (per worker)
### Saving and investment
- Saving (per worker) \( y - c \) = \( sy \)
- National income identity is \( y = c + i \)
  - Rearrange to get: \( i = y - c = sy \)
  - (investment = saving, like in chap. 3!)
- Using the results above, \( i = sy = sf(k) \)

### Output, consumption, and investment
- Output per worker, \( y \)
- Capital per worker, \( k \)
- Consumption per worker, \( c \)
- Investment per worker, \( i \)

### Depreciation
- Depreciation per worker, \( \delta_k \)
  - \( \delta = \) the rate of depreciation
  - \( \delta = \) the fraction of the capital stock that wears out each period

### Capital accumulation
- The basic idea: Investment increases the capital stock, depreciation reduces it.
- Change in capital stock \( \Delta k \) = investment - depreciation
  - \( \Delta k = i - \delta k \)
  - Since \( i = sf(k) \), this becomes:
    \[
    \Delta k = sf(k) - \delta k
    \]

### The equation of motion for \( k \)
- The Solow model’s central equation
- Determines behavior of capital over time...
- ...which, in turn, determines behavior of all of the other endogenous variables because they all depend on \( k \).
  - E.g.,
    - income per person: \( y = f(k) \)
    - consumption per person: \( c = (1-s) f(k) \)

### The steady state
- \( \Delta k = sf(k) - \delta k \)
- If investment is just enough to cover depreciation \( [sf(k) = \delta k] \),
  - then capital per worker will remain constant: \( \Delta k = 0 \).
  - This occurs at one value of \( k \), denoted \( k' \), called the steady state capital stock.
The steady state

Moving toward the steady state

Investment and depreciation

Capital per worker, \( k \)

\[ \Delta k = sf(k) - \delta k \]

Investment
depreciation

Capital per worker, \( k \)

Summary:
As long as \( k < k^* \), investment will exceed depreciation, and \( k \) will continue to grow toward \( k^* \).
Now you try:

Draw the Solow model diagram, labeling the steady state $k^*$.

On the horizontal axis, pick a value greater than $k^*$ for the economy's initial capital stock. Label it $k_1$.

Show what happens to $k$ over time. Does $k$ move toward the steady state or away from it?

An increase in the saving rate

An increase in the saving rate raises investment...

...causing $k$ to grow toward a new steady state:

Prediction:

- Higher $s \Rightarrow$ higher $k^*$.
- And since $y = f(k)$,
  higher $k^*$ $\Rightarrow$ higher $y^*$.
- Thus, the Solow model predicts that countries with higher rates of saving and investment will have higher levels of capital and income per worker in the long run.

International evidence on investment rates and income per person

The Golden Rule: Introduction

- Different values of $s$ lead to different steady states. How do we know which is the "best" steady state?
- The "best" steady state has the highest possible consumption per person: $c^* = (1-s) f(k^*)$.
- An increase in $s$
  - leads to higher $k^*$ and $y^*$, which raises $c^*$
  - reduces consumption's share of income $(1-s)$, which lowers $c^*$.
- So, how do we find the $s$ and $k^*$ that maximize $c^*$?

The Golden Rule capital stock

$k^*_{\text{gold}}$ = the Golden Rule level of capital, the steady state value of $k$ that maximizes consumption.

To find it, first express $c^*$ in terms of $k^*$:

\[
c^* = y^* - i^* = f(k^*) - f(k) - \delta k^*
\]

In the steady state:

\[
i^* = \delta k^* \quad \text{because } \Delta k = 0.
\]
**CHAPTER 7 Economic Growth I**

**slide 39**

Then, graph \( f(k^*) \) and \( \delta k^* \), look for the point where the gap between them is biggest.

The Golden Rule capital stock steady state output and depreciation

**CHAPTER 7 Economic Growth I**

**slide 40**

The Golden Rule capital stock steady-state output and depreciation

\[ c^* = f(k^*) - \delta k^* \]

is biggest where the slope of the production function equals the slope of the depreciation line:

**CHAPTER 7 Economic Growth I**

**slide 41**

The transition to the Golden Rule steady state

- The economy does NOT have a tendency to move toward the Golden Rule steady state.
- Achieving the Golden Rule requires that policymakers adjust \( s \).
- This adjustment leads to a new steady state with higher consumption.
- But what happens to consumption during the transition to the Golden Rule?

**CHAPTER 7 Economic Growth I**

**slide 42**

Starting with too much capital

If \( k^* > k^*_\text{gold} \) then increasing \( c^* \) requires a fall in \( s \). In the transition to the Golden Rule, consumption is higher at all points in time.

**CHAPTER 7 Economic Growth I**

**slide 43**

Starting with too little capital

If \( k^* < k^*_\text{gold} \) then increasing \( c^* \) requires an increase in \( s \). Future generations enjoy higher consumption, but the current one experiences an initial drop in consumption.

**CHAPTER 7 Economic Growth I**

**slide 44**

Population growth

- Assume that the population (and labor force) grow at rate \( n \) (\( n \) is exogenous.)
  \[ \frac{\Delta L}{L} = n \]
- EX: Suppose \( L = 1,000 \) in year 1 and the population is growing at 2% per year (\( n = 0.02 \)).
  Then \( \Delta L = nL = 0.02 \times 1,000 = 20 \), so \( L = 1,020 \) in year 2.

**CHAPTER 7 Economic Growth I**
Break-even investment

- \((\delta + n)k = \text{break-even investment}\), the amount of investment necessary to keep \(k\) constant.
- Break-even investment includes:
  - \(\delta k\) to replace capital as it wears out
  - \(nk\) to equip new workers with capital
  (Otherwise, \(k\) would fall as the existing capital stock would be spread more thinly over a larger population of workers.)

The equation of motion for \(k\)

- With population growth, the equation of motion for \(k\) is
  \[
  \Delta k = s f(k) - (\delta + n)k
  \]

The Solow model diagram

- The Solow model diagram illustrates the relationship between investment, break-even investment, and capital per worker, \(k\).

The impact of population growth

- An increase in \(n\) causes an increase in break-even investment, leading to a lower steady-state level of \(k\).

Prediction:

- Higher \(n \Rightarrow\) lower \(k^*\).
- And since \(y = f(k)\), lower \(k^* \Rightarrow\) lower \(y^*\).

Thus, the Solow model predicts that countries with higher population growth rates will have lower levels of capital and income per worker in the long run.

International evidence on population growth and income per person

- The graph shows the relationship between population growth and income per person in 2000 (log scale), indicating a negative correlation.
The Golden Rule with population growth

To find the Golden Rule capital stock, express $c^*$ in terms of $k'$:

$$c^* = y^* - i^* = f(k') - (\delta + n)k'$$

$c^*$ is maximized when $MPK = \delta + n$ or equivalently,

$$MPK - \delta = n$$

In the Golden Rule steady state, the marginal product of capital net of depreciation equals the population growth rate.

Alternative perspectives on population growth

The Malthusian Model (1798)
- Predicts population growth will outstrip the Earth’s ability to produce food, leading to the impoverishment of humanity.
- Since Malthus, world population has increased sixfold, yet living standards are higher than ever.
- Malthus omitted the effects of technological progress.

The Kremerian Model (1993)
- Posits that population growth contributes to economic growth.
- More people = more geniuses, scientists & engineers, so faster technological progress.
- Evidence, from very long historical periods:
  - As world pop. growth rate increased, so did rate of growth in living standards
  - Historically, regions with larger populations have enjoyed faster growth.

Chapter Summary

1. The Solow growth model shows that, in the long run, a country’s standard of living depends
   - positively on its saving rate
   - negatively on its population growth rate
2. An increase in the saving rate leads to
   - higher output in the long run
   - faster growth temporarily
   - but not faster steady state growth.
3. If the economy has more capital than the Golden Rule level, then reducing saving will increase consumption at all points in time, making all generations better off.
   If the economy has less capital than the Golden Rule level, then increasing saving will increase consumption for future generations, but reduce consumption for the present generation.
